

# Windows Brute-Force Detection using Splunk

---

**Subject:** Windows Brute-Force Detection using Splunk

**Incident ID:** IR-2025-1220-006

**PREPARED BY:**

**Vignesh K.**

*SOC Analyst / Security Researcher*

**CERTIFICATIONS:** Google Cybersecurity Professional

**REPORT DATE:** December 20, 2025

# 1. Project Overview and Goal

- **Overview:** This project demonstrates detection of brute-force authentication attempts against a Windows 11 system using Splunk SIEM.

## 2. Technical Environment and Tools

The technical components and tools used for this assessment are detailed below.

| Component       | Description           | Detail            |
|-----------------|-----------------------|-------------------|
| Target System   | The victim server.    | Windows 11        |
| Attacker System | The attacker machine. | Kali Linux.       |
| Primary Tools   | SIEM                  | Splunk Enterprise |

## 3. Attack Simulation

- SMB authentication attempts from Kali
- Multiple failed login attempts generated
- Windows logged Event ID 4625

## 4. Detection

- Splunk was used to detect brute-force behavior by correlating multiple failed login events.-  
\*\*Splunk Query Logic:\*\* The provided Splunk Search Processing Language (SPL) query (`index=\* EventCode=4625 | stats count by Account`) aggregates all failed logon events (Event ID 4625) across all indexes. The `stats count by Account` command then groups these events by the target `Account` name and counts the total number of failed attempts for each unique account within the search timeframe.
-

- - **Threshold Setting:** A security analyst would then review the counts. A high count (e.g., > 10 failed attempts within a short window like 5 minutes) for a single account is a strong indicator of a brute-force attack.
- 
- - **Visualisation:** This data can be visualized in a Splunk dashboard (e.g., a bar chart or a single value panel) to provide real-time monitoring of failed login trends and quickly identify accounts under attack.
- 
- - **Refinement for Alerting:** For operational security, this base query is typically refined to include time windows and a specific threshold to trigger an automated alert (as noted in the security recommendations). For example, `... | where count > 5` and scheduled to run every 5 minutes.
- 

## 5. SPL Query

```
index=* EventCode=4625 | stats count by Account_
```

The core Search Processing Language (SPL) query used for detection is:

`index=* EventCode=4625 | stats count by Account` This query is a foundational step in identifying brute-force activity.

### Detailed Explanation of SPL Components

`index=* EventCode=4625`

This is the initial filtering stage.

- **index=\***: Instructs Splunk to search across *all* configured indexes. In a production environment, this should be narrowed down (e.g., `index=windows_security`) for performance.
- **EventCode=4625**: This is the critical filter. Windows Security Event ID 4625 specifically corresponds to a **"An account failed to log on"** event. Filtering by this ID ensures that only failed authentication attempts are analyzed, which is the signature of a brute-force attack.

## | stats count by Account

This is the command that performs the aggregation and statistical analysis.

- **| (Pipe)**: Used to pipe the results of the previous command (the filtered failed logon events) into the next command.
- **stats**: A reporting command used to calculate statistics on the search results.
- **count**: The specific statistical function used, which calculates the total number of events.
- **by Account**: Specifies that the **count** should be grouped by the unique value in the **Account** field. The **Account** field typically holds the name of the user account that the attacker was trying to log into.

## Result Interpretation

The output of this query is a simple table showing every unique account that experienced a failed login attempt during the search time frame, along with the total number of attempts (**count**) associated with that account. A security analyst immediately looks for an unusually high **count** value associated with any single **Account**, as this strongly suggests a programmatic, rapid-fire brute-force attempt rather than typical user error. The time range of the search is implicitly critical to this interpretation.

## 6. Security Recommendations (Next Steps)

Based on the detection results, the following remediation measures and security enhancements are recommended:

- **HIGH: Enforce Account Lockout Policy:** Implement a strict Group Policy Object (GPO) to lock out user accounts after a small number of consecutive failed login attempts (e.g., 3-5).
- **HIGH: Monitor and Alert:** Refine the existing Splunk query into a scheduled alert that triggers a high-priority incident when the threshold of failed logins is met. This alert should notify the SOC team immediately.
- **MEDIUM: Implement Multi-Factor Authentication (MFA):** Where possible, deploy MFA for all critical accounts and services to mitigate the risk of password-based attacks.
- **MEDIUM: Network Segmentation:** Isolate critical servers using network segmentation to limit the attack surface and prevent attacker lateral movement.

## 7. Conclusion

This project successfully validated the capability of using Splunk to detect common Windows security threats such as SMB-based brute-force attacks. The correlation of Event ID 4625 is a foundational detection control. Immediate action on the security recommendations, particularly the automated alerting and account lockout policies, is essential to harden the system against this threat.

## 8. Evidence

### 8.1 Eventviewer\_4625

#### Account For Which Logon Failed:

|                 |           |
|-----------------|-----------|
| Security ID:    | S-1-0-0   |
| Account Name:   | fakeuser  |
| Account Domain: | WORKGROUP |

#### Failure Information:

|                 |                                    |
|-----------------|------------------------------------|
| Failure Reason: | Unknown user name or bad password. |
| Status:         | 0xC000006D                         |
| Sub Status:     | 0xC0000064                         |

#### Process Information:

|                      |     |
|----------------------|-----|
| Caller Process ID:   | 0x0 |
| Caller Process Name: | -   |

#### Network Information:

|                         |                |
|-------------------------|----------------|
| Workstation Name:       | KALI           |
| Source Network Address: | 192.168.31.110 |
| Source Port:            | 33932          |
